As has been pointed out in several studies (Wenzel 1994, Schenkl & Wright 2011, Jefferson & Putter 2013), historical mixed texts are an interesting, yet still widely unexplored, source of information concerning language use in multilingual societies of medieval Europe. One reason for the dearth of linguistically oriented studies in the field is the lack of digital corpora. This contribution presents an approach to the creation of a part-of-speech tagged and parsed corpus of historical code-switching. The aim of the project is to create gold standard data for the systematic testing of existing code-switching theories, and to provide guidelines for the annotation of historical mixed language texts.

To set the scene we will briefly address automatized language recognition (cf. Solorio et al. 2008) and the choice of an appropriate tagset, small enough to make cross-linguistic generalizations yet at the same time detailed enough to provide enough information to the user (cf. Petrov et al. 2012; Jamatia et al. 2015). Then we will zoom in on theoretical considerations involved in the selection of a parser. This includes the choice of a theoretical model of grammar and its implications for possible analyses that then can(not) be carried out on the corpus. Even though the theoretical code-switching model we adopt is based on constituency, dependency-based parsers have clearly yielded superior results so far. If time permits we will also address the pros and cons of either using two parsers, one for each language, or one joined parser which then has to be designed to capture the grammatical structures of more than one language at a time (cf. Goyal et al. 2003).

To illustrate our points we present results from a collection of macaronic sermons (Horner 2006, Middle English and Latin, ca. 100,000 words), a text genre containing diverse code-switching and language mixing structures which is thus highly informative both for multilingualism research and for computational linguistics. In the following excerpt Middle English word forms appear in roman, Latin word forms in italic. Non-distinctive elements at switch-points are marked by an underscore:

Sepe men fallen in despare pro losse of good and dignite. Si vis nauigare sauelich in istis maribus et euadere hec pericula, oportet strike seil in primo mari and cast ankur in secundo. Tunc pro combinacione partium et processu sermonis, dico primo: strike sail in þe perlus see of welth and prosperite þat þi schip ouerturne not with þe wynde of pride and vanite. Cast ankur in God dum nauigas mare aduersitatis þat þou periche not be despair for losse of good or dignite. Qwo so hath sailed both þes sees and an biden bittur stormys, experiencia docet eum to telle of many perels. (Horner 2006, p. 521)

In conclusion we will address some problematic items like particles, adverbs and idioms which are well-known challenges to computational linguistics, and point out possible solutions, balancing our linguistic ambition against the potential and limitations of automatic language processing.
